

## MTHS24 – Exercise sheet 11

Morning: Christian Fischer

Afternoon:

Friday, 26 July 2024

---

### Lecture material

#### Discussed topics:

- Functional methods
- Dynamical Chiral Symmetry Breaking
- Spectra of conventional and exotic hadrons
- (optional:  $g-2$ , form factors,...)

#### References:

### Exercises

#### 11.1 Diquarks

Write down spin, color and flavour wave functions for a scalar and an axialvector diquark built from

- (a) two light quarks (what is the resulting isospin ?)
- (b) two strange, charm or bottom quarks
- (c) a heavy-(not-so-heavy) combination such as  $bc$ ,  $bs$  or  $cs$ .

*Hint: carefully think about symmetries...*

**Solution: I.) Scalar diquarks:**

Spin  $S=0 \rightarrow \frac{1}{\sqrt{2}} (\uparrow\downarrow - \downarrow\uparrow)$  and antisymmetric

Color: From Young-Tableaux we find  $3 \otimes 3 = 6 \oplus \bar{3}$  and  $\bar{3}$  is antisymmetric, while 6 is symmetric.

Thus we need an antisymmetric flavour wave function together with  $\bar{3}$ -color and a symmetric flavour wave function together with 6-color.

We obtain for  $\bar{3}$ -color:

- (a)  $\frac{1}{\sqrt{2}} (ud - du)$  and we have  $I=0$ .
- (b) not possible
- (c)  $\frac{1}{\sqrt{2}} (bc - cb)$  and analogously for the others.

We obtain for 6-color:

- (a)  $\{\frac{1}{\sqrt{2}} (ud + du), uu, dd\}$  and we have  $I=1$ .
- (b)  $ss, cc, bb$
- (c)  $\frac{1}{\sqrt{2}} (bc + cb)$  and analogously for the others.

**II.) Axialvector diquarks:**

Spin  $S=1 \rightarrow \{\frac{1}{\sqrt{2}} (\uparrow\downarrow + \downarrow\uparrow), \uparrow\uparrow, \downarrow\downarrow\}$  and symmetric

Color: Same as above. But now we need a symmetric flavour wave function together with  $\bar{3}$ -color and an antisymmetric flavour wave function together with 6-color.

Thus, flavour/color combinations are interchanged as compared to scalar diquark.

**11.2 Four-quark states**

Now think about a four-quark state with two heavy quarks and two light anti-quarks in the two flavour combinations  $bb\bar{q}\bar{q}$  and  $bc\bar{q}\bar{q}$ . Suppose, the quarks and antiquarks are arranged in scalar (S) and axialvector (A) diquarks. Which diquark combinations are possible for the following quantum numbers?

- (a)  $I(J) = 0(1)$

**Solution:**  $J = 1 \rightarrow$  we need at least one axialvector diquark, i.e. only combinations  $AA, SA, AS$  are possible.

color  $3 \otimes \bar{3}$ :

$I = 0 \rightarrow$  light diquark needs to be S  $\rightarrow$  heavy diquark needs to be A and indeed, this is possible for both,  $bb\bar{q}\bar{q}$  and  $bc\bar{q}\bar{q}$ .

color  $6 \otimes \bar{6}$ :

$I = 0 \rightarrow$  light diquark needs to be A  $\rightarrow$  heavy diquark can be S or A. Only S is possible for  $bb\bar{q}\bar{q}$ , whereas S and A are possible for  $bc\bar{q}\bar{q}$ .

- (b)  $I(J) = 1(1)$

**Solution:**  $J = 1 \rightarrow$  we need at least one axialvector diquark, i.e. only combinations  $AA, SA, AS$  are possible.

color  $3 \otimes \bar{3}$ :

$I = 1 \rightarrow$  light diquark needs to be A. For  $bb\bar{q}\bar{q}$ , the heavy diquark also needs to be A (since S is not possible). For  $bc\bar{q}\bar{q}$  both, S and A are possible.

color  $6 \otimes \bar{6}$ :

$I = 1 \rightarrow$  light diquark needs to be S  $\rightarrow$  heavy diquark needs to be A. This is not possible for  $bb\bar{q}\bar{q}$ , but allowed for  $bc\bar{q}\bar{q}$ .

- (c)  $I(J) = 0(0)$

**Solution:**  $J = 0 \rightarrow$  we need either  $SS$  or  $AA$  (from rules of adding angular momenta).

color  $3 \otimes \bar{3}$ :

$I = 0 \rightarrow$  light diquark needs to be  $S \rightarrow$  heavy diquark also needs to be  $S$ . This is not possible for  $bb\bar{q}\bar{q}$ , but allowed for  $bc\bar{q}\bar{q}$ .

color  $6 \otimes \bar{6}$ :

$I = 0 \rightarrow$  light diquark needs to be  $A \rightarrow$  heavy diquark also needs to be  $A$ . Again, this is not possible for  $bb\bar{q}\bar{q}$ , but allowed for  $bc\bar{q}\bar{q}$ .

*Hint: again carefully think about symmetries...*

### 11.3 Pion Bethe-Salpeter Equation

The Bethe-Salpeter vertex function  $\Gamma_\pi$  of a pion can be expressed most generally by

$$\Gamma_\pi(P, p) = \sum_{i=1}^4 f_i(P, p) T_i \quad (1)$$

with tensors  $T_1 = \gamma_5 \mathbf{1}$ ,  $T_2 = \gamma_5 \hat{P}$ ,  $T_3 = \gamma_5 \not{p}$  and  $T_4 = \gamma_5 [\hat{P}, \not{p}]$  in Dirac-space. Here we use the normalised total momentum  $\hat{P}$  of the pion and the orthogonalised relative momentum  $p$  between quark and antiquark, i.e.  $\hat{P} \cdot \hat{P} = 1$  and  $p \cdot P = 0$ .

The Pauli-Lubanski vector (see e.g. Maggiore, chapter 2.7) can be used to determine the spin and angular momentum quantum numbers of these tensors in the rest frame of the pion. Its square can be separated in a part referring to angular momentum and a part referring to spin:

$$L^2 = 2p^\alpha \frac{\partial}{\partial p^\alpha} + \left( p_T^\alpha p_T^\beta - p_T^2 T_p^{\alpha\beta} \right) \frac{\partial}{\partial p^\alpha} \frac{\partial}{\partial p^\beta} \quad (2)$$

$$[S^2]_{i,j}^{k,l} = \frac{3}{2} \mathbf{1}_{i,j} \otimes \mathbf{1}_{k,l} - \frac{1}{2} \left( \gamma_T^\mu \gamma_5 \hat{P} \right)_{i,j} \otimes \left( \hat{P} \gamma_5 \gamma_T^\mu \right)_{k,l} \quad (3)$$

Here,  $\gamma_T^\mu = \gamma^\mu - \hat{P}^\mu \hat{P}$ ,  $p_T^\alpha = p^\alpha - \hat{P}^\alpha p \cdot P$  and  $T_p^{\alpha\beta} = \delta^{\alpha\beta} - p^\alpha p^\beta / p^2$ .

- (a) Show that  $T_1$  and  $T_2$  are s-waves (eigenvalue 0 of  $L^2$ ), whereas  $T_3$  and  $T_4$  are p-waves (eigenvalue 1 of  $L^2$ ).

**Solution:**

$$L^2 T_1 = L^2 \gamma_5 \mathbf{1} = 0 \quad (4)$$

$$L^2 T_2 = L^2 \gamma_5 \hat{P} = 0 \quad (5)$$

$$L^2 T_3 = L^2 \gamma_5 \not{p} = \gamma_5 2p^\alpha \gamma^\mu \delta_{\alpha\mu} = 2\gamma_5 \not{p} \quad (6)$$

$$L^2 T_4 = L^2 \gamma_5 [\hat{P}, \not{p}] = \gamma_5 2[\hat{P}, \gamma^\mu \delta_{\alpha\mu}] = 2\gamma_5 [\hat{P}, \not{p}] \quad (7)$$

- (b) Show that  $T_1$  has eigenvalue 0 wrt.  $S^2$ . (The same is true for  $T_2$ .)

*Hint:  $\gamma_T^\mu \gamma_T^\mu = 3$*

**Solution:**

$$[S^2]_{i,j}^{k,l} [\gamma_5]_{j,k} = \frac{3}{2} [\gamma_5]_{i,l} - \frac{1}{2} [\gamma_T^\mu \gamma_5 \hat{P} \gamma_5 \hat{P} \gamma_5 \gamma_T^\mu]_{i,l} \quad (8)$$

$$= \frac{3}{2} [\gamma_5]_{i,l} - \frac{1}{2} [\gamma_T^\mu \gamma_T^\mu \gamma_5]_{i,l} \quad (9)$$

$$= \frac{3}{2} [\gamma_5]_{i,l} - \frac{3}{2} [\gamma_5]_{i,l} = 0 \quad (10)$$

- (c) Show that  $T_3$  has eigenvalue 1 wrt.  $S^2$ . (The same is true for  $T_4$ , but this calculation is rather lengthy...)

*Hint: Use  $p \cdot P = 0$  and  $\not{p} \gamma_T^\mu = -\gamma_T^\mu \not{p} + 2p^\mu$*

**Solution:**

$$[S^2]_{i,j}^{k,l}[\gamma_5 \not{p}]_{j,k} = \frac{3}{2}[\gamma_5 \not{p}]_{i,l} - \frac{1}{2}[\gamma_T^\mu \gamma_5 \hat{P} \gamma_5 \not{p} \hat{P} \gamma_5 \gamma_T^\mu]_{i,l} \quad (11)$$

$$= \frac{3}{2}[\gamma_5 \not{p}]_{i,l} - \frac{1}{2}[\gamma_T^\mu \hat{P} \not{p} \hat{P} \gamma_T^\mu \gamma_5]_{i,l} \quad (12)$$

$$= \frac{3}{2}[\gamma_5 \not{p}]_{i,l} - \frac{1}{2}[\gamma_T^\mu \gamma_T^\mu \gamma_5 \not{p}]_{i,l} + [\gamma_T^\mu p_\mu \gamma_5] \quad (13)$$

$$= \left(\frac{3}{2} + \frac{3}{2} - 1\right)[\gamma_5 \not{p}]_{i,l} = 2[\gamma_5 \not{p}]_{i,l} \quad (14)$$
